			dt:dt, tostring: tostring, name:name
		};
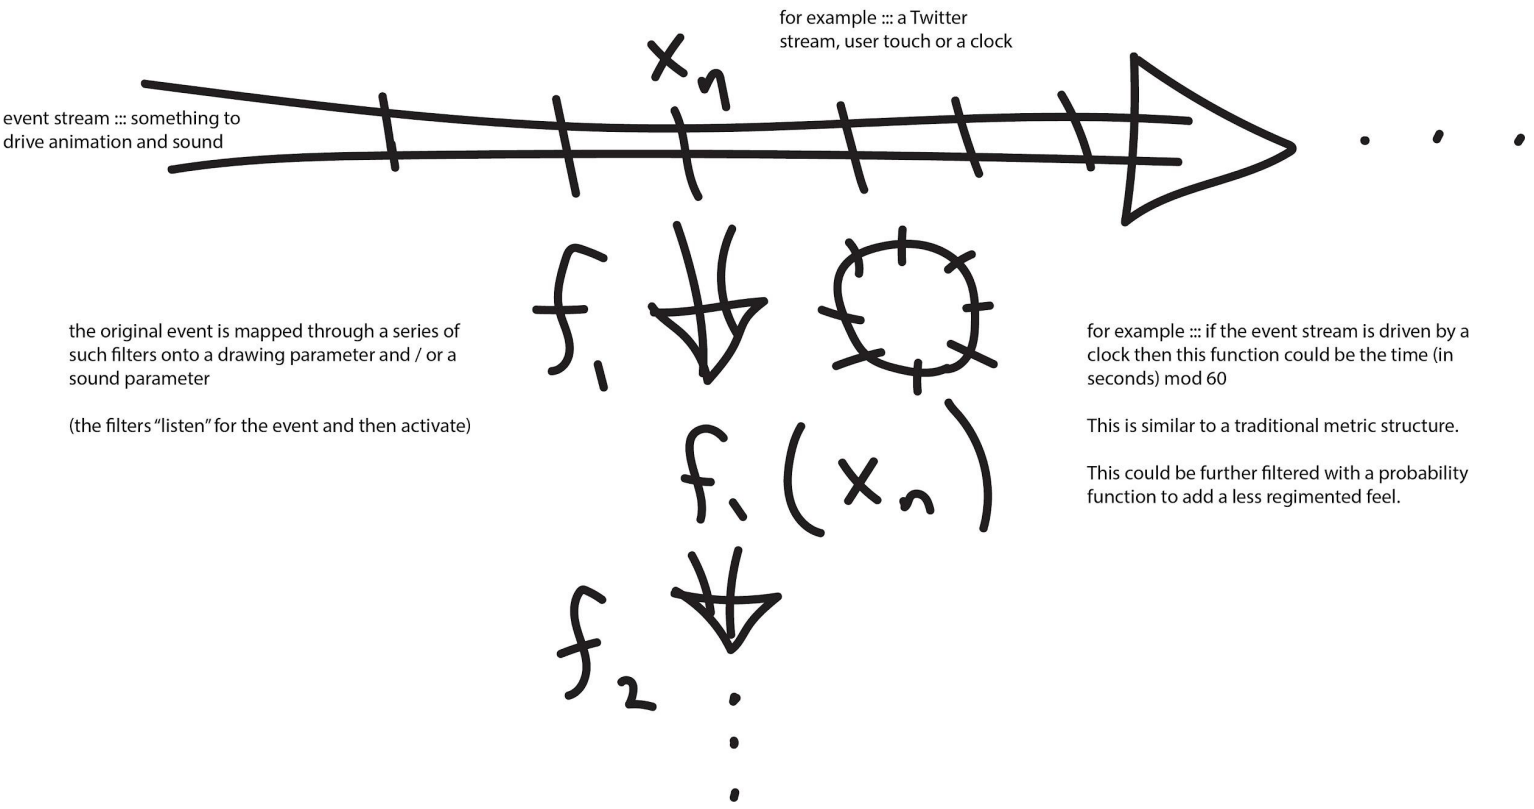
		z.streams[name] = Kefir.combine([z.streams["tick"].filter( e => e.t%dt===0 && z.score.soundplaying && z.tools.ra
			.scan( (state, e) => {
				state.tick = e.tick;
```

figure 21 : sound maps : functional programming (streams ::: filter / map / fold)



the original event is mapped through a series of such filters onto a drawing parameter and / or a sound parameter

(the filters "listen" for the event and then activate)

for example ::: if the event stream is driven by a clock then this function could be the time (in seconds) mod 60

This is similar to a traditional metric structure.

This could be further filtered with a probability function to add a less regimented feel.

figure 22 : sound maps : vibrating strings / pitch transformations
